Introduction to Correlation and Regression Analysis In this section we will first discuss correlation analysis, which is used to quantify the association between two continuous variables (e.g., between an independent and a dependent variable or between two independent variables).

Introduction to Correlation and Regression Analysis

Correlation is described as the analysis which lets us know the association or the absence of the relationship between two variables 'x' and 'y'. On the other end, Regression analysis, predicts the value of the dependent variable based on the known value of the independent variable, assuming that average mathematical relationship between two or more variables.

Correlation and Regression: A Comparative Study

Recall that both correlation and regression measure the relationship between two variables. Correlation comes first and simply quantifies the relationship or co-movements between variables. Next, if the researcher assumes that changes in one variable can help predict changes another, then we can use linear regression.

The regression equation is often more useful than the correlation coefficient. It enables us to predict y from x and gives us a better summary of the relationship between the two variables. If, for a particular value of x, x_i , the regression equation predicts a value of y fit , the prediction error is .

What is the key differences between correlation and ...

Correlation and regression analysis are related in the sense that both deal with relationships among variables. The correlation coefficient is a measure of linear association between two variables. Values of the correlation coefficient are always between -1 and $+1$.
